Theoretical and computational bounds for $m$-cycles of the $3n+1$ problem

John Simons (Groningen)∗ Benne de Weger (Eindhoven)∗∗

version 1.44†, August 31, 2010

Abstract

An $m$-cycle of the $3n+1$-problem is defined as a periodic orbit with $m$ local minima. In this article we derive lower and upper bounds for the cycle length and the elements of (hypothetical) $m$-cycles. In particular, we prove that there do not exist nontrivial $m$-cycles for $1 \leq m \leq 75$. Our proofs are based on transcendental number theory, computational diophantine approximation techniques, and a not straightforward generalization of the approach of Steiner and Simons on 1-cycles and 2-cycles respectively.

Mathematics Subject Classification: 11B83

Acknowledgements

We want to express our gratitude to Ray Steiner for useful remarks on the manuscript, and to Rob Tijdeman for acting as trait d’union.

The main improvements in this version 1.44 over version 1.3 are due to impressive computational work by Tomás Oliveira e Silva.

1 Introduction

1.1 General

The $3n+1$-problem is a well known problem in elementary number theory. Let $n$ be a natural number, and consider the sequence generated by iteration of $T(n) = \frac{1}{2}(3n+1)$ if $n$ is odd, $T(n) = \frac{1}{2}n$ is $n$ is even. Numerical verification indicates that for all natural numbers finally the cycle $\{1, 2\}$ appears. A proof of this so called $3n+1$-conjecture is lacking sofar, in spite of various approaches to the problem. See Lagarias [La] and Wirsching [Wi] for extensive overviews on the $3n+1$-problem.

We call a cycle an $m$-cycle if the numbers in it appear in $m$ sequences, each consisting of an increasing subsequence of odd numbers, followed by a decreasing subsequence of even numbers.

Let such an $m$-cycle contain in total $K$ odd numbers and $L$ even numbers. The cycle $\{1,2\}$ is a 1-cycle, and in 1977 Steiner [St] proved that other 1-cycles do not exist. Any $m$-cycle containing natural numbers greater than 2 is called nontrivial, and in 2004 Simons [Si] proved the nonexistence of nontrivial 2-cycles.

In this paper we generalize the approach of Steiner and Simons, and for an arbitrary value of $m$ we derive the following:

1. An upper bound for $\Lambda = (K + L) \log 2 - K \log 3$ that is exponential in $K$, following from estimates for $m$-cycles;
2. A lower bound for $\Lambda$ that is subexponential in $K$, following from transcendence theory;
3. Upper bounds for $K$ and $L$, and for the minimal element $x_{\min}$ of the cycle, following from comparing the upper and lower bounds for $\Lambda$. These upper bounds appear to be exponential in $m$.

Further, for 'small' and 'medium' values of $m$ we derive

4. Lower bounds for $K$ and $L$, following from brute force computations and diophantine approximation techniques (continued fractions, lattice basis reduction) applied to $\log 3/\log 2$.

For 'small' values of $m$ (up to $m \leq 75$) the lower bound of 4. is larger than the upper bound of 3. For 'medium' values of $m$ (up to $m \leq 515620$) the diophantine approximation techniques lead to an improvement of the upper bounds for $K$, $L$ and $x_{\min}$, which remain exponential in $m$.

1.2 $m$-Cycles of the $3n+1$-problem

We study periodic sequences $\{T^k(n)\}$, i.e. we do not consider unbounded sequences. Without loss of generality we’re not interested in nonperiodic parts, so if necessary we replace $n$ by some $T^k(n)$ which is in the periodic part. Hence we may assume that the sequence is purely periodic, i.e. there exists an integer $p \geq 1$ such that in the periodic sequence $\{n, T(n), T^2(n), \ldots, T^{p-1}(n), T^p(n), \ldots\}$ it is the case that $T^p(n) = n$ (we may take $p$ minimal with this property, but for our arguments that is not essential). We consider only the period, i.e. $\{n, T(n), T^2(n), \ldots, T^{p-1}(n)\}$. We further may assume that $T^0(n) = n$ is at a local minimum in the sequence (not necessarily the global minimum).

Let there be $m$ local minima in the periodic sequence, with indices $t_0, t_1, \ldots, t_{m-1}$ such that $0 = t_0 < t_1 < \ldots < t_{m-1} < p$. Then there are also $m$ local maxima, say with indices $s_0, s_1, \ldots, s_{m-1}$. As each maximum lies in between two minima, we may assume $0 = t_0 < s_0 < t_1 < s_1 < \ldots < t_{m-1} < s_{m-1} < p - 1$. We call such a periodic sequence an $m$-cycle. Define $x_i, y_i$ as the values of the local minima and maxima, viz.

\[ x_i = T^{t_i}(n), \quad y_i = T^{s_i}(n). \]

We put $k_i = s_i - t_i$ for $i = 0, \ldots, m - 1$, and $\ell_i = t_{i+1} - s_i$ for $i = 0, \ldots, m - 2$, and $\ell_{m-1} = p + t_0 - s_{m-1}$. Further we put

\[ K = \sum_{i=0}^{m-1} k_i, \quad L = \sum_{i=0}^{m-1} \ell_i. \]

The sequence thus starts with an odd number $x_0$, increases in $k_0$ steps until an even number $y_0$ is encountered, then decreases in $\ell_0$ steps until an odd number $x_1$ is encountered, again increases in $k_1$ steps until an even number $y_1$ is encountered, etcetera.

We call the $m$-fold repeated 1-cycle $\{1,2,1,2,\ldots,1,2\}$ the trivial $m$-cycle.
1.3 Crandall’s lemma

For a nontrivial \( m \)-cycle, put \( x_{\text{min}} = \min\{x_0, x_1, \ldots, x_{m-1}\} \). By \( X_0 \) we denote a lower bound for \( x_{\text{min}} \) that is known to be true at a certain point in time. At the moment of writing this (August 31, 2010) it is known from extensive computations by Tomás Oliveira e Silva [OS] that

\[
x_{\text{min}} > X_0 = 5 \cdot 2^{60} > 5.7646 \cdot 10^{18}.
\]

Eric Roosendaal’s independent computations [Ro] have reached \( x_{\text{min}} > 890 \cdot 2^{50} > 1.0020 \cdot 10^{18} \). The computations are going on\(^1\). The rate of improvement over the period June 2004 to January 2009 has been on average approximately \( 3.5 \cdot 10^{15} \) per day (see [OS]).

Let \( \delta = \log 3 / \log 2 = 1.5849 \ldots \) Throughout this paper this number \( \delta \) plays a central role. Let its continued fraction expansion be given by \( \delta = [a_0, a_1, a_2, \ldots] = [1, 1, 1, 2, 2, 3, 1, 5, 2, 23, 2, 2, 1, 1, 55, \ldots] \), with convergents \( p_n/q_n = [a_0, a_1, a_2, \ldots, a_n] \) for \( n = 0, 1, \ldots \).

Crandall [Cr] showed the following result.

**Lemma 1 (Crandall, 1978)**

If \( p_n/q_n \) is any convergent to \( \delta \) with \( n \geq 4 \), then for a nontrivial \( m \)-cycle

\[
K > \min \left\{ q_n, \frac{2x_{\text{min}}}{q_n + q_{n+1}} \right\}.
\]

As a consequence, we have the following result.

**Corollary 2**

\[ K > 9.0240 \cdot 10^8. \]

**Proof.** This follows immediately from Lemma 1, the present value for \( X_0 \), and the fact that \( q_{19} = 397 \, 573 \, 379, q_{20} = 6 \, 189 \, 245 \, 291, \) and \( q_{21} = 6 \, 586 \, 818 \, 670. \)

In this paper we generalize Crandall’s Lemma for \( m \)-cycles, which in general results in sharper lower bounds for \( K \).

1.4 Known results on the nonexistence of cycles

Steiner [St] proved in 1977 the nonexistence of nontrivial 1-cycles. He assumes the existence of a 1-cycle with \( k \) odd numbers and \( \ell \) even numbers, and proves the following partial results:

1. An inequality for the ratio \( \frac{k + \ell}{k} \);

2. A numerical lower bound for \( k \), from which it follows that \( \frac{k + \ell}{k} \) must be a convergent from the continued fraction expansion of \( \delta \);

3. An upper bound for \( k \) from a theorem of Baker [Ba] on linear forms in two logarithms;

4. A (very effective) lower bound for the partial quotients in the continued fraction expansion of \( \delta \).

\(^1\)It seems that Oliveira da Silva has stopped since January 2009.
Numerical calculation of partial quotients then shows that the only 1-cycle that satisfies these conditions is the trivial one.

Crucial in Steiner’s proof for the nonexistence of 1-cycles is (implicitly) the inequality \( 0 < (k + \ell) \log 2 - k \log 3 < \frac{1}{x_{\min}} \). The right hand side is exponentially small in \( k \), since the existence of \( k \) successive odd numbers starting with \( x_0 \) implies that \( x_0 = a 2^k - 1 \geq 2^k - 1 \). Hence \( \frac{k + \ell}{k} \) must be a convergent of \( \delta \) for \( k \geq 5 \). This inequality has a “natural” generalization for 2-cycles in the form of \( 0 < (K + L) \log 2 - K \log 3 < \frac{1}{x_0} + \frac{1}{x_1} \), however the convergent argument fails because \( k_0 \) or \( k_1 \) can be small even if \( K \) is large. As has been remarked by Lagarias [La], the result of Steiner’s proof seems rather weak, considering the strength of the underlying number theory.

Simons [Si] proved in 2004 the nonexistence of nontrivial 2-cycles. By exploiting the average values of \( k_0 \) and \( k_1 \) he derived for the expression \( \frac{1}{x_0} \) an effective upper bound of the form \( ce^{-d(K + L)} \), where \( c \) and \( d \) are positive constants. He generalizes Steiner’s approach and derives

1. A generalized inequality for the ratio \( \frac{K + L}{K} \);

2. A numerical lower bound for \( K \), from which it follows that \( \frac{K + L}{K} \) must be a convergent from the continued fraction expansion of \( \delta \);

3. An upper bound for \( K \) by applying a theorem of Laurent, Mignotte and Nesterenko [LMN] on linear forms in two logarithms;

4. A lower bound for the partial quotients in the continued fraction expansion of \( \delta \).

Steiner’s original numerical verification finally shows that the only 2-cycle that satisfies these conditions is the trivial 2-cycle \( \{1, 2, 1, 2\} \).

This approach however fails to prove the nonexistence of \( m \)-cycles for \( m > 2 \), because then the coefficient \( d \) in Simons’ upper bound becomes negative, which makes the upper bound ineffective.

Many partial results on the (non)existence of cycles for the \( 3n + 1 \)-problem, as well as for generalizations, have been conjectured and proved by applying a scala of theoretical methods, see Lagarias [La] and Wirsching [Wi]. In particular, using transcendence methods like we do, Brox [Br] showed that there are only finitely many \( m \)-cycles with \( m < 2 \log K \), and from that he derived the result that for each \( m \) there are only finitely many \( m \)-cycles (see Theorem 3(a) below).

### 1.5 Lower and upper bounds on cycle elements and lengths

In this paper we extend the cited results of Steiner [St] and Simons [Si], and prove that for each \( m \) there are only finitely many \( m \)-cycles. Indeed, extending the result of Brox [Br], for \( m \)-cycles we derive explicit upper bounds, depending only on \( m \), for the values of \( K \), \( L \) and \( x_{\min} \).

By doing extensive computations we also derive new lower bounds for these values. Then, combining upper and lower bounds, we prove that there exist no nontrivial \( m \)-cycles for \( m \leq 75 \). For \( m = 76 \) and \( m = 77 \) we give possible solutions, which will be excluded when exterior computations à la [OS] and [Ro] lead to new values for \( X_0 \). For \( m \geq 78 \) we derive explicit lower and upper bounds for the cycle length and for the numbers in the cycle.

Our main result is the following theorem.
Theorem 3 (Main Theorem)
For an $m$-cycle for the $3n+1$-problem, let $K, L, x_{\text{min}}$ be defined as above.

(a) (Brox [Br]) For any $m$ there are only finitely many $m$-cycles.

(b) For $1 \leq m \leq 75$ there do not exist nontrivial $m$-cycles.

(c) For $76 \leq m \leq 77$ the only possible nontrivial $m$-cycles satisfy $x_{\text{min}} > 5.7646 \cdot 10^{18}$ and

<table>
<thead>
<tr>
<th>$m$</th>
<th>$K = \text{117,972,833,293,231,014}$</th>
<th>$L = \text{69,009,683,580,368,485}$</th>
<th>$x_{\text{min}} &lt; \text{6.2044} \cdot 10^{18}$</th>
</tr>
</thead>

<td></td>
</tr>
</tbody>
</table>

(d) For $m \geq 78$ the possible nontrivial $m$-cycles satisfy

if $78 \leq m \leq 90$ then

$1.1173 \cdot 10^{17} < K < 1.3993 \cdot 10^{19} \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 0.33593}$

$6.1715 \cdot 10^{16} < L < 0.81850 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m - 0.20028}$

$5.7646 \cdot 10^{18} < x_{\text{min}} < 3.3914 \cdot 10^{m/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 5.8265}$

if $91 \leq m \leq 515\,619$ then

$7.5311 \cdot 10^{11} < K < 1.4784 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 0.39905}$

$4.4054 \cdot 10^{11} < L < 0.86480 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m - 0.14525}$

$5.7646 \cdot 10^{18} < x_{\text{min}} < 5.1825 \cdot 10^{17} \cdot m^{2/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 17.764}$

if $515\,620 \leq m \leq 527\,875\,034$ then

$9.0240 \cdot 10^{8} < K < 1.5109 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 2.7153}$

$5.2787 \cdot 10^{8} < L < 8.8379 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 2.1791}$

$5.7646 \cdot 10^{18} < x_{\text{min}} < 6.1260m^{1/3}$

if $m \geq 527\,875\,035$ then

$1.7095 m < K < 1.5108 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 2.7152}$

$m \leq L < 8.8372 \cdot m^{4/3} \cdot \delta^{(c)} < e^{0.46057m + \log m + 2.1790}$

$5.7646 \cdot 10^{18} < x_{\text{min}} < 6.1255m^{1/3}$

In the cases $91 \leq m \leq 527\,875\,034$ the lower bounds can be a bit more fine-tuned (see Corollary 11 below). The upper bounds in terms of powers of $e$ are provided to ease comparison.

We expect that, with current technology and efforts, $m = 76$ and $m = 77$ can be expected to be solved within 30 years, and that $m = 78$ and beyond may take considerably longer to be finished.

2 Conditions for the existence of an $m$-cycle

2.1 The chain equation

We first describe an $m$-cycle in more detail.

The existence of $k_i$ successive odd numbers starting with $x_i$ implies that $x_i \equiv -1 \pmod{2^k_i}$, i.e. $x_i = 2^{k_i}a_i - 1$ for some integer $a_i \geq 1$. Going up from a local minimum $x_i$ to the next local maximum $y_i$ is now expressed in the formula $y_i = 3^{\delta_i}a_i - 1$. Then going down to the next local
minimum $x_{i+1}$ is done by $y_i = 2^i x_{i+1}$ (with $x_m = x_0$). Putting this together we arrive at the 'chain equation'

$$3^k a_i - 1 = 2^{k_{i+1}} + 2^{\ell_i} a_{i+1} - 2^{\ell_i}$$

for $i = 0, 1, ..., m - 1$. If we put $x_m = x_0$, i.e. $a_m = a_0$ and $k_m = k_0$, we impose the existence of an $m$-cycle.

Note that the chain equation with $m = 1$ is at the heart of Steiner’s result [St]. From now on we take $m \geq 2$.

### 2.2 Integral and rational solutions

When we fix $k_i, \ell_i$ in the chain equation, we have $m$ linear equations in the $m$ variables $a_i$. We get the 'matrix equation'

$$M \begin{pmatrix} a_0 \\ a_1 \\ \vdots \\ a_{m-1} \end{pmatrix} = \begin{pmatrix} 2^{k_0} - 1 \\ 2^{k_1} - 1 \\ \vdots \\ 2^{k_{m-1}} - 1 \end{pmatrix},$$

with the matrix $M$ defined as

$$M = \begin{pmatrix} -3^{k_0} & 2^{k_0+\ell_0} & 0 & \cdots & 0 \\ 0 & -3^{k_1} & 2^{k_2+\ell_1} & \cdots & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & -3^{k_{m-2}} & 2^{k_{m-1}+\ell_{m-2}} \\ 2^{k_0+\ell_{m-1}} & 0 & \cdots & 0 & -3^{k_{m-1}} \end{pmatrix}.$$ 

Put

$$\Delta = 2^{K+L} - 3^K.$$

Then $\text{det}(M) = (-1)^{m-1}\Delta$. Applying linear algebra, in fact using an argument of Böhm and Sontacchi [BS], we proceed to find the inverse matrix $M^{-1}$. Put $\Delta M^{-1} = (m_{i,j})_{i,j=0,1,\ldots,m-1}$, $a_{i,j} = \sum_{h=1+i}^{j-1} k_h$, $\beta_{i,j} = \sum_{h=1+i}^{j} \ell_h$, where we take $j^* = j$ if $i \leq j$, and $j^* = j + m$ if $i > j$, where the indices of $k_h, \ell_h$ are taken modulo $m$. Then we have $m_{i,j} = 2^{\alpha_{i,j} + \beta_{i,j}} 3^{k_i - k_{i-j}}$, as is easily verified. In particular $m_{i,j} > 0$, and then the matrix equation and $a_i > 0$ imply that $\Delta > 0$.

It follows that $m$-cycles are in one-to-one correspondence with solutions $k_i, \ell_i, a_i$ of the matrix equation, with $k_i, \ell_i, a_i$ all positive integers. For a given combination of $k_i$ and $\ell_i$ at most one such solution exists (there is exactly one solution with $a_i$ rational\(^2\), but in most cases the $a_i$ are not integral). It follows that when we know upper bounds for $K$ and $L$, there are only finitely many rational solutions left that can in principle be enumerated.

\(^2\)Rational solutions with common denominator $q$ correspond to solutions of the $3n + q$-problem.
3 Conditions on $K$ and $m$ from a linear form in logarithms

3.1 Introducing $\Lambda$

Like in Steiner’s and Simons’ proofs [St], [Si], the basis of our final result is a linear form in logarithms of integers, that for large $m$-cycles turns out to be too small to be possible. This linear form is

$$\Lambda = (K + L) \log 2 - K \log 3.$$

3.2 A first inequality for $\Lambda$

Lemma 4

$$0 < \Lambda < \sum_{i=1}^{m} \frac{1}{x_i}.$$

Proof. Rewrite the chain equation as

$$\frac{2^{k_i+1} a_i+1}{3^{k_i}} \frac{a_i}{a_i} = 1 + \frac{2^{l_i} - 1}{3^{k_i} a_i}.$$

Taking the product over all $i = 0, 1, \ldots, m - 1$, and using the cyclicity, we get

$$\frac{2^{K+L}}{3^K} = \prod_{i=0}^{m-1} \left(1 + \frac{2^{l_i} - 1}{3^{k_i} a_i}\right).$$

We now apply $\log(1 + x) < x$ to each term in the product, and thus obtain

$$0 < \Lambda = \sum_{i=0}^{m-1} \log \left(1 + \frac{2^{l_i} - 1}{3^{k_i} a_i}\right) < \sum_{i=0}^{m-1} \frac{2^{l_i} - 1}{3^{k_i} a_i}.$$

The result now follows by $3^{k_i} a_i = y_i + 1 > y_i = 2^{l_i} x_i + 1 > (2^{l_i} - 1) x_i + 1$, and the cyclicity. \(\square\)

Corollary 5

$$0 < \Lambda < \frac{m}{x_{\text{min}}} \leq \frac{m}{X_0}.$$

Proof. Use Lemma 4 together with $x_i \geq x_{\text{min}} \geq X_0$. \(\square\)

3.3 Chaining

Now we will show that all $x_i$ are exponentially large in terms of $K$ (or, equivalently, $K + L$). To do so, we first show that all $x_i$ are of about the same size, by 'chaining' them.

Put $b = \frac{1 + X_0^{-1}}{2^{1/5}}$. With the present value of $X_0$ we have $b = 0.64576 \ldots$. In fact, the dependence on $X_0$ is negligible.
Lemma 7

For all \( i = 0, 1, \ldots, m - 1 \) we have \( x_{i+1} < b^\delta x_i^\delta \).

Proof. We have

\[
x_{i+1} = \frac{y_i}{2^{k_i}} < \frac{y_i + 1}{2^{k_i}} = \frac{3^{k_i}a_i}{2^{k_i}} \leq \frac{3^{k_i}b_i}{2} = \frac{3^{k_i}x_i}{2} = \left( \frac{3}{2} \right)^{k_i}x_i + 1.
\]

Now use \( a_i \geq 1 \) and \( x_i \geq X_0 \) to get

\[
x_{i+1} < \frac{1}{2} (2^{k_i}a_i)^{\delta - 1} (x_i + 1) = \frac{1}{2} (x_i + 1)^\delta \leq \frac{1}{2} (1 + X_0^{-1})^\delta x_i^\delta = b^\delta x_i^\delta.
\]

\( \square \)

Note that the inequality of Lemma 6 holds cyclically. As a result we can estimate all \( x_i \) in terms of one \( x_i \) of our choice, say \( x_0 \).

3.4 Another inequality for \( \Lambda \)

Put

\[
c_m = 2^m \frac{2m}{\delta + 1} b^\delta x_m^\delta.
\]

With the present value of \( X_0 \) we find that \( c_m \) decreases from \( c_2 = 0.76479 \ldots \) to \( b^\delta(\delta - 1) = 0.30576 \ldots \). When we also let \( X_0 \) tend to infinity, we get \( c_m \to 2^{-1/(\delta - 1)} = 0.30576 \ldots \). Anyway, \( c_m < 0.30577 \) for \( m \geq 30 \).

As a consequence of Lemmas 4 and 6 we can now estimate \( \Lambda \) in terms of its coefficients, i.e. \( K \).

Lemma 7

\[ 0 < \Lambda < mc_m 2^{-\frac{\delta - 1}{\delta + 1}} K. \]

Proof. Lemma 6 implies \( x_i < b^{\delta + \delta^2 + \ldots + \delta^m} x_0^\delta \) for \( i = 1, 2, \ldots, m - 1 \). Hence

\[
\prod_{i=0}^{m-1} x_i < \left( \frac{b^\delta x_0^\delta}{m} \right)^{\delta + \delta^2 + \ldots + \delta^m} = b^{\frac{\delta + \delta^2 + \ldots + \delta^m}{\delta + 1}} x_0^{\frac{\delta + \delta^2 + \ldots + \delta^m}{\delta + 1}}.
\]

On the other hand, also

\[
\prod_{i=0}^{m-1} x_i = \prod_{i=0}^{m-1} \frac{x_i + 1}{x_i} \geq (1 + X_0^{-1})^{-m} \prod_{i=0}^{m-1} 2^{k_i} a_i \geq (1 + X_0^{-1})^{-m} 2^K,
\]

where we simply estimated \( a_i \geq 1 \). Hence

\[
x_0^{-\frac{\delta + \delta^2 + \ldots + \delta^m}{\delta + 1}} < (1 + X_0^{-1})^m b^{\frac{\delta + \delta^2 + \ldots + \delta^m}{\delta + 1}} 2^K = c_m^{-1} 2^K.
\]

Now we choose \( x_0 = x_{\min} \), which we can do because of the cyclicity. Corollary 5 to Lemma 4 then shows that

\[ 0 < \Lambda < \frac{m}{x_{\min}} < mc_m 2^{-\frac{\delta - 1}{\delta + 1}} K. \]
Though strictly speaking the inequality of Lemma 7 depends on the value of $X_0$, this dependence is negligible.

4 Conditions on $K$ and $m$ from continued fractions

4.1 A useful lemma

A consequence of Corollary 5 to Lemma 4 is we have sharp lower and upper bounds for the ratios $\frac{K+L}{K}$, $\frac{K+L}{L}$, and $\frac{K}{L}$. This is useful not only in this section but also further in this paper.

**Lemma 8**

\[
\frac{\delta K}{\delta - 1} < \frac{K + L}{K} < 1.000001 \frac{\delta K}{\delta - 1},
\]
\[
0.999999 \frac{\delta}{\delta - 1} L < \frac{K + L}{L} < \frac{\delta}{\delta - 1} L,
\]
\[
0.999999 \frac{1}{\delta - 1} L < K < \frac{1}{\delta - 1} L.
\]

**Proof.** By Corollary 5 and the present value of $X_0$ we have

\[
0 < K + L - K \delta < \frac{m}{X_0 \log 2} \leq \frac{K}{X_0 \log 2} < 10^{-18} K,
\]

and the inequalities readily follow. □

4.2 Continued fraction results

Recall that we denote by $\frac{p_n}{q_n}$ the $n$th convergent to $\delta$. Continued fraction theory shows that convergents are best approximations, i.e. any other approximation with smaller denominator is worse. Further necessary and sufficient inequalities for convergents are available. Indeed, we have the following results, the proofs of which can be found in many introductory texts on number theory (see e.g. [HW, Chapter 10]).

**Lemma 9**

(a) If $\frac{p}{q}$ is a rational approximation to $\delta$ satisfying $|p - q \delta| < \frac{1}{2q}$, then $\frac{p}{q}$ is a convergent.

(b) $|p_n - q_n \delta| > \frac{1}{q_n + q_{n+1}} > \frac{1}{(a_{n+1} + 2)q_n}$.

(c) If $\frac{p}{q}$ is a rational approximation to $\delta$, and if $q \leq q_n$, then $|p - q \delta| \geq |p_n - q_n \delta|$.

(d) If $n$ is odd then $p_n - q_n \delta > 0$; if $n$ is even then $p_n - q_n \delta < 0$.

4.3 A generalization of Crandall’s Lemma to $m$-cycles

With Corollary 5 we now can derive a result like Crandall’s Lemma 1, which gives a lower bound for $K$ that depends on $m$. 
Lemma 10
If \( q_n + q_{n+1} \leq (\log 2) \frac{X_0}{m} \), then \( K > q_n \).

Proof. Assume \( K \leq q_n \). By Lemma 9(c) and (b)

\[
\Lambda = (\log 2)|\Lambda - K\delta| \geq (\log 2)|p_n - q_n\delta| > \frac{\log 2}{q_n + q_{n+1}} \geq \frac{m}{X_0},
\]

which contradicts Corollary 5. \( \Box \)

Applying this with each \( m \) the maximal \( n \) that satisfies the condition, leads to the following result.

Corollary 11

\[
\begin{align*}
\text{If} & \quad m \leq 6 \quad \text{then} \quad K > q_3 > 2.6711 \times 10^{17}, \\
\text{if} & \quad 7 \leq m \leq 10 \quad \text{then} \quad K > q_3 > 1.3044 \times 10^{17}, \\
\text{if} & \quad 11 \leq m \leq 29 \quad \text{then} \quad K > q_2 > 6.2345 \times 10^{15}, \\
\text{if} & \quad 30 \leq m \leq 33 \quad \text{then} \quad K > q_1 > 5.7509 \times 10^{15}, \\
\text{if} & \quad 34 \leq m \leq 64 \quad \text{then} \quad K > q_0 > 4.8361 \times 10^{14}, \\
\text{if} & \quad 65 \leq m \leq 64 \quad \text{then} \quad K > q_{28} > 4.3116 \times 10^{14}, \\
\text{if} & \quad 4308 \leq m \leq 8262 \quad \text{then} \quad K > q_{28} > 5.2449 \times 10^{13}, \\
\text{if} & \quad 8263 \leq m \leq 62412 \quad \text{then} \quad K > q_{27} > 1.1571 \times 10^{13}, \\
\text{if} & \quad 62413 \leq m \leq 225312 \quad \text{then} \quad K > q_{26} > 6.1624 \times 10^{12}, \\
\text{if} & \quad 225313 \leq m \leq 345300 \quad \text{then} \quad K > q_{25} > 5.4093 \times 10^{12}, \\
\text{if} & \quad 345301 \leq m \leq 648401 \quad \text{then} \quad K > q_{24} > 7.5311 \times 10^{11}, \\
\text{if} & \quad 648402 \leq m \leq 4486354 \quad \text{then} \quad K > q_{23} > 1.3752 \times 10^{11}, \\
\text{if} & \quad 4486355 \leq m \leq 19683486 \quad \text{then} \quad K > q_{22} > 6.5470 \times 10^{10}, \\
\text{if} & \quad 19683487 \leq m \leq 55451899 \quad \text{then} \quad K > q_{21} > 6.5868 \times 10^{9}, \\
\text{if} & \quad 55451900 \leq m \leq 312750582 \quad \text{then} \quad K > q_{20} > 6.1892 \times 10^{9}, \\
\text{if} & \quad 312750583 \leq m \leq 527875034 \quad \text{then} \quad K > 9.0240 \times 10^8, \\
\text{if} & \quad 527875035 \leq m \quad \text{then} \quad K > 1.7095m.
\end{align*}
\]

Proof. All lines but the last two follow immediately from Lemma 10. The one but last line is Corollary 2 to Crandall’s original Lemma 1. The last line follows by Lemma 8 from the trivial observation that \( L \geq m \). \( \Box \)

Note that the bounds for \( m \) in Corollary 11 depend heavily on the value of \( X_0 \). Also note that Corollary 11 implies \( K > 6.8580 \times 10^{16} \frac{1}{m} \).

5 Application of Transcendence Theory

Now that we know that \( \Lambda \) is exponentially small in terms of its coefficients, we can invoke deep but explicit results from transcendence theory, which tell us that linear forms in logarithms of integers cannot be too small in terms of their coefficients. Since Steiner published his paper [St] with essentially the same idea of applying transcendence theory to prove the nonexistence of nontrivial 1-cycles, transcendence theory has made substantial progress. For general linear forms \( x \log a + y \log b \) with \( x, y \in \mathbb{Z} \) and \( a, b \in \mathbb{N} \) the best results today are the result of Laurent, Mignotte and Nesterenko [LMN] for small \( x, y \), and for large \( x, y \) that of Matveev [Ma] (see also Nesterenko [Ne]). For our specific case \( x \log 2 + y \log 3 \) however, the result of Rhin [Rh] is best. From it we derive the following estimate.

Lemma 12

\[
\Lambda > e^{-13.3(0.46057+\log K)}.
\]
Theoretical and computational bounds for $m$-cycles of the $3n + 1$ problem

**Proof.** We apply the Proposition on p. 160 of [Rh] with $u_0 = 0$, $H = u_1 = K + L$, and $u_2 = -K$. Together with Lemma 8 the result follows.

As a consequence of Lemma 12 we can also estimate the global minimum of an $m$-cycle in terms of $K$.

**Corollary 13**

$$x_{\text{min}} < m e^{13.3(0.46057+\log K)}.$$  

**Proof.** Apply Corollary 5 and Lemma 12.

---

6 Upper bounds for $K$, $L$ and $x_{\text{min}}$

6.1 Initial upper bound

Clearly Lemmas 7 and 12 are contradictory when $K$ is large enough. In other words, they provide an upper bound for $K$, and then by Lemma 8 and Corollary 13 also for $L$ and $x_{\text{min}}$.

**Lemma 14** Let $x = K_1(m)$ be the largest solution of

$$e^{-13.3(0.46057+\log x)} = mc_m 2^{-\frac{m-1}{m}x}.$$  

Then

$$K < K_1(m).$$

**Proof.** Immediate from Lemmas 7 and 12 and the definition of $K_1(m)$.

Let $k_1(m) = K_1(m)/(mc_m)$. Note that $k_1(m)$ is a decreasing function that for increasing $m$ tends to the constant $\frac{13.3\log 2}{\log 2(\delta-1)} = 15.107 \ldots$ as $m \to \infty$. Indeed:

</table>

The dependence of $K_1(m)$ on $X_0$ is negligible.

For each $m$ we now have proved Theorem 3(a), that there are only finitely many $m$-cycles. Moreover, we can derive explicit upper and lower bounds for $K$, $L$ and $x_{\text{min}}$, as stated in Theorem 3(d). For $m \leq 515 619$ we can obtain better results in the next section.

**Proof of Theorem 3(d) for $m \geq 515 620$**. The upper bound for $K$ follows from Lemma 14, and the observation that $k_1$ is a decreasing function of $m$. The lower bound for $K$ follows by Corollary 11. The bounds for $L$ and $x_{\text{min}}$ follow by combining this with Lemma 8 and Corollary 13.

Moreover, we can combine Lemma 14 with the generalized Crandall Lemma 10, to prove that for small $m$ there are no solutions at all. The next lemma proves a part of Theorem 3(b).
Lemma 15
There are no nontrivial $m$-cycles for $2 \leq m \leq 63$.

**Proof.** By Lemma 14, for $m \leq 63$ we have $K < K_1(m) \leq K_1(63) < 4.8181 \cdot 10^{15}$. This contradicts the $K > 5.7509 \cdot 10^{15}$ from Corollary 11 to the generalized Crandall Lemma 10. $$\square$$

Note that Corollary 2 to Crandall's original Lemma 1 gives a result only for $m \leq 30$.

The maximum value of $m$ in Lemma 15 does depend heavily on the value of $X_0$, in the sense that any substantial improvement of the value of $X_0$ immediately leads to an improvement of the upper bound for $m$ for which the proof works.

### 6.2 Reduced upper bound

Next we use, like Steiner [St], a continued fraction argument to find a better upper bound for $K$.

We computed the continued fraction of $\delta$ up to $a_{2000001}$. Using Mathematica 7.0 on a 2.1GHz Intel Core2 Duo T7500 processor this computation took less than 5 seconds.

Let $x = J_2(m)$ be the largest solution of

$$mc_m 2^{- \frac{j-1}{x}} = \frac{\log 2}{2x}.$$ 

Lemmas 7 and 9(a) imply that $\frac{K + L}{K}$ is a convergent to $\delta$ whenever $K > J_2(m)$. Note that only convergents with odd index are of interest, as the sign of $p_n - q_n \delta$ alternates (Lemma 9(d)), and we have $\Lambda > 0$.

In view of Lemma 9(b), of particular interest are partial quotients $a_n$ that are champions in the sense that $a_k < a_n$ whenever $k < n$, for even $k, n$.

For each $m$ let $n(m)$ be the index $n$ of the smallest champion for which $K_1(m) < q_{n-1}$. Then we define $A(m) = \max \{a_0, a_2, \ldots, a_{n(m)-2}\}$. Clearly $A(m)$ is the champion before $n(m)$. Indeed, we have

<table>
<thead>
<tr>
<th>$m$</th>
<th>$n(m)$</th>
<th>$A(m)$</th>
<th>$K_1(m) &lt; q_{n(m)-1}$</th>
</tr>
</thead>
<tbody>

<td>816</td>
<td>2.0804 \cdot 10^{667}</td>
</tr>
<tr>
<td>817</td>
<td>1340</td>
<td>1340</td>
<td>2.1843 \cdot 10^{772}</td>
</tr>
<tr>
<td>1341</td>
<td>7009</td>
<td>7009</td>
<td>9.1127 \cdot 10^{406}</td>
</tr>
<tr>
<td>7010</td>
<td>1143</td>
<td>1143</td>
<td>1.0938 \cdot 10^{234}</td>
</tr>
<tr>
<td>11144</td>
<td>54234</td>
<td>54234</td>
<td>5.5425 \cdot 10^{10853}</td>
</tr>
<tr>
<td>54235</td>
<td>315502</td>
<td>315502</td>
<td>5.5425 \cdot 10^{10853}</td>
</tr>
<tr>
<td>315503</td>
<td>515619</td>
<td>515619</td>
<td>3.0475 \cdot 10^{103140}</td>
</tr>
</tbody>
</table>

For $m \geq 515620$ we can in principle find corresponding values for $A(m)$ when we compute more partial quotients.

With the part of the continued fraction that we have at our disposal, we can derive a sharper upper bound for all $m \leq 515619$, as follows. Let $x = K_2(m)$ be the largest solution of

$$mc_m 2^{- \frac{j-1}{x}} = \frac{\log 2}{(A(m) + 2)x}.$$ 

Note that $j_2(m) = J_2(m)/(m \delta^m)$ is a bounded function, that tends to $\log \delta/((\delta - 1) \log 2) = 1.1358\ldots$ when $m \to \infty$. Also put $k_2(m) = K_2(m)/(m \delta^m)$. As we don’t know how $A(m)$ will
grow when \( m \) increases, we don’t know the exact behaviour of \( k_2(m) \), but most probably it will also tend to \( \log \delta/(\delta - 1) \log 2 = 1.1358 \ldots \) when \( m \to \infty \). Indeed:

<table>
<thead>
<tr>
<th>( m )</th>
<th>( j_2(m) &lt; J_2(m) &lt; )</th>
<th>( k_2(m) &lt; K_2(m) &lt; )</th>

</tbody>
</table>

The next lemma now gives a better upper bound for \( K \) in the range for which the continued fraction argument can be applied, given the part of the continued fraction we have computed.

**Lemma 16**

For \( 64 \leq m \leq 515619 \) a possible \( m \)-cycle satisfies \( K < K_2(m) \).

**Proof.** Note that \( J_2(m) < K_2(m) \) for all \( m \), so we may assume \( K > J_2(m) \). Then by the definition of \( J_2 \), Lemma 7 implies \( \Lambda < \frac{\log 2}{2K} \), and so Lemma 9(a) shows that \( \frac{K + L}{K} = \frac{p_n}{q_n} \) for some odd \( n \).

From Lemma 14 we have \( K < K_1(m) < q_{n(m)-1} \), implying \( n \leq n(m) - 2 \). Hence \( a_{n+1} \leq A(m) \).

The definition of \( K_2 \), Lemmas 9(b) and 7 then imply \( K < K_2(m) \). \( \square \)

A computation\(^3\) shows that there are only 68 values of \( m \) between 64 and 515619 for which there is a convergent \( \frac{p_n}{q_n} \) with odd index and \( J_2(m) < q_n < K_2(m) \). In all other cases \( q_n > J_2(m) \) implies \( q_n > K_2(m) \). As \( J_2 \) and \( K_2 \) are relatively close, we do not elaborate.

As a consequence of Lemma 16 we can now prove a further part of Theorem 3(d), giving improved upper bounds for \( K \), \( L \) and \( x_{\text{min}} \) in the case of \( 91 \leq m \leq 515619 \). For \( m \leq 90 \) we wil achieve even better results in the next section.

**Proof of Theorem 3(d) for \( 91 \leq m \leq 515619 \).** The upper bound for \( K \) follows from Lemma 16, and the observation that \( k_2(m) < 1.4784 \) (note that \( k_2(m) \) is a decreasing function, except when \( A(m) \) jumps to the next champion). The lower bound for \( K \) follows by Corollary 11. The bounds for \( L \) follow by combining this with Lemma 8.

\(^3\)In fact, this part of our computations was by far the most time consuming, taking 92 minutes.
For $x_{\text{min}}$ we now can find a rather sharp upper bound, as follows. Let $n$ be the index such that $q_{n-1} < K \leq q_n$. By $K < K_2(m) \leq K_2(515\,619) < 2.2916 \cdot 10^{103.139} < 7.5013 \cdot 10^{103.139} < q_{199\,998}$ we have $n \leq 199\,998$. From the continued fraction we find that for this range $(a_n + 1)(a_n + 1 + 2) \leq 24\,298\,288$. Now Corollary 5 and Lemma 9(c) and (b) show that $x_{\text{min}} < m \Lambda < m(\log 2) |p_n - q_n\delta| < m(a_n + 1)(a_n + 1 + 2) q_n \log 2 < m(a_n + 1)(a_n + 1 + 2) K \log 2 < 24\,298\,288 \log 2 - mK$, where we used $q_n = a_n q_n - 1 + q_n - 2 < (a_n + 1)q_n - 1$. The bound for $x_{\text{min}}$ now follows at once. 

The improvement we reached here for the bound of $x_{\text{min}}$ is substantial. Though the improvement of the bounds for $K$ and $L$ is to some extent marginal (we cannot improve on the dominating term $\delta^m$), the improvement becomes significant for small $m$, when we combine Lemma 16 with the generalized Crandall Lemma 10, to get a result improving on Lemma 15. The next lemma proves another part of Theorem 3(b).

**Lemma 17**

*There are no nontrivial $m$-cycles for $2 \leq m \leq 68$.***

**Proof.** In view of Lemma 15 we assume $m \geq 64$. By Lemma 16, for $m \leq 68$ we have $K < K_2(m) \leq K_2(68) < 4.2776 \cdot 10^{15}$. This contradicts $K > 5.7509 \cdot 10^{15}$ from Corollary 11. 

The maximum value of $m$ in Lemma 17 does depend on the value of $X_0$, in the sense that any substantial improvement of the value of $X_0$ leads to an improvement of the upper bound for $m$ for which the proof works.

## 7 Elimination of small solutions

### 7.1 Convergents

The classic approach now is to show, based on Lemma 9(a) as well as on refinements for e.g. "secondary convergents", that possible solutions in certain ranges are (secondary) convergents, and then to check all such (secondary) convergents for Corollary 5. Instead we will use an approximation lattice method, that can be seen as a more powerful variant of the continued fraction method. See [dW, Section 1.4 and Chapter 3] for some background on approximation lattices.

### 7.2 Lattices

We look for solutions in an "approximation lattice", as follows.

For a vector $\mathbf{x} = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$ we define the norm $\|\mathbf{x}\|$ as $\|\mathbf{x}\| = \max \{|x_1|, |x_2|\}$.

Put $C = \left\lceil \frac{X_0 \log 2}{m} K_2(m) \right\rceil$. Now let

$$\Gamma = \begin{pmatrix} 1 & 0 \\ \lfloor C\delta \rfloor & C \end{pmatrix},$$

where $\lfloor \cdot \rfloor$ stands for rounding towards the nearest integer. Then we look at the lattice of the $\mathbb{Z}$-linear combinations of the columns of $\Gamma$. For a solution $K, L$ satisfying Corollary 5, Lemma 7 and Lemma 16 we look at the lattice point

$$\mathbf{x} = \Gamma \begin{pmatrix} -K \\ K + L \end{pmatrix} = \begin{pmatrix} -K \\ \Lambda_0 \end{pmatrix},$$
where $\Lambda_0 = (K + L)C - K[C\delta]$ is an approximation of $\frac{C}{\log 2} \Lambda$. Indeed, by Lemma 16 we have

$$\left| \Lambda_0 - \frac{C}{\log 2} \Lambda \right| \leq K |C\delta - [C\delta]| \leq \frac{1}{2} K_2(m).$$

It follows by Corollary 5 and the definition of $C$ that

$$|\Lambda_0| \leq \frac{1}{2} K_2(m) + \frac{C}{\log 2} |\Lambda| < \frac{1}{2} K_2(m) + \frac{C}{\log 2} \frac{m}{X_0} \leq K_2(m).$$

It follows that we only have to search for lattice points with norm at most $K_2(m)$.

To achieve this efficiently, we compute (by the Euclidean, i.e. continued fraction, algorithm) a reduced basis of the lattice. Let $\Gamma_{\text{red}}$ be a matrix with as columns this reduced basis. The lattice point $x$ can be expressed in the reduced basis as $x = \Gamma_{\text{red}} z$ for some $z \in \mathbb{Z}^2$. Due to the reducedness of the lattice basis, the number of points to be searched is approximately $K_2(m)^2 C \approx \frac{m}{X_0} K_2(m)$. A brute force search for points $z \in \mathbb{Z}^2$ such that $\|\Gamma_{\text{red}} z\| \leq K_2(m)$ is therefore efficient when $K_2(m)$ is not much larger than $\frac{X_0}{m}$. Each lattice point found can be checked for fulfilling Corollary 5 and Lemma 7.

Doing this search for $69 \leq m \leq 90$ we found the following results.

**Lemma 18**

(a) With $69 \leq m \leq 75$ there are no nontrivial $m$-cycles.

(b) With $76 \leq m \leq 77$ the only possible nontrivial $m$-cycles satisfy

\[
\begin{array}{|c|c|c|c|c|}
\hline
m & K & L & \text{falls when } X_0 \geq \text{year} \\
\hline
76, 77 & 117972833293231014 & 69009683580368485 & \{5.39, 5.46\} \cdot 2^{10} & 2011 \\
76, 77 & 124207383220472977 & 72656661496678846 & \{9.39, 9.52\} \cdot 2^{10} & 2015 \\
76, 77 & 130441933147714940 & 76303639412989207 & \{36.8, 37.3\} \cdot 2^{10} & 2040 \\
77 & 254649316368187917 & 148960300909668053 & 7.58 \cdot 2^{10} & 2013 \\
\hline
\end{array}
\]

(c) With $78 \leq m \leq 90$ the only possible nontrivial $m$-cycles satisfy

\[
\begin{array}{|c|c|c|c|c|}
\hline
m & \# \text{ solutions} & K \geq & K \leq & \text{falls when } X_0 \geq \text{year} \\
\hline
78 & 6 & 11173828336989051 & 397560349370386783 & 447 \cdot 2^{19} & 2409 \\
79 & 9 & 11173828336989051 & 658444215665816663 & 452 \cdot 2^{20} & 2414 \\
80 & 12 & 11173828336989051 & 1049770015108961483 & 458 \cdot 2^{20} & 2419 \\
81 & 19 & 11173828336989051 & 1453564914406590229 & 464 \cdot 2^{20} & 2424 \\
82 & 33 & 11173828336989051 & 251580402937035638 & 469 \cdot 2^{20} & 2429 \\
\hline
\end{array}
\]

For $76 \leq m \leq 77$ we give with each solution the minimal value for $X_0$ that has to be reached to show that the solution does not correspond to an $m$-cycle. We also give the year in which this is expected to happen when the current rate of checking per day $3.5 \cdot 10^{15}$ values for $x_{\text{min}}$ is continued, according to [OS], resuming the computations on January 1, 2011.

For $78 \leq m \leq 90$ we only give for each $m$ the number of solutions found, and the minimal and maximal $K$. For $m \leq 82$ we also give the minimal value for $X_0$ that has to be reached to show that the solutions do not correspond to an $m$-cycle, and the year in which this is expected to happen. For $m \geq 83$ this year is always further away than 4400.

The entire computation for the proof of Lemma 18 took 3.2 seconds.
As a result we can now complete the proof of Theorem 3.

Proof of Theorem 3(b), (c) and (d) for \( m \leq 90 \). (b) follows at once from Lemma 18(a). The values in (c) and upper bound in (d) for \( K \) follow from Lemma 18. The lower bound for \( K \) follows by Lemma 18. The bounds for \( L \) follow by combining this with Lemma 8. In (c) the upper bound for \( x_{\min} \) is derived from Corollary 5.

In (d) the upper bound for \( x_{\min} \) is derived as in the above proof of the other part of Theorem 3(d), as follows. Let \( n \) be the index such that \( q_{n-1} < K \leq q_n \). By \( K < K_2(m) \leq K_2(90) < 1.3388 \cdot 10^{20} < 2.0563 \cdot 10^{20} < q_{43} \) we have \( n \leq 43 \). From the continued fraction we find that \( (a_n + 1)(a_{n+1} + 2) \leq 168 \). Hence \( x_{\min} < \frac{168}{\log 2} mK \).

8 Conclusion

In Theorem 3, it is of interest to note that the border \( m = 75/76 \) between (b) and (c) is directly related to the size of the lower bound \( X_0 \) for \( x_{\min} \) that comes from external brute force computations, see [OS] and [Ro]. We indicated above when this border will be crossed, assuming that these computations continue at the present speed, and no new ideas emerge. We expect, as indicated in Lemma 18, that \( m = 76 \) and \( m = 77 \) can be expected to be solved within 25 years, and that \( m = 78 \) and beyond will take a considerably larger effort to finish.

The border \( m = 77/78 \) between Theorem 3(c) and (d) depends only on the amount of space one is willing to spend on listing candidate solutions that cannot yet be ruled out.

The border \( m = 90/91 \) in Theorem 3(d) depends directly on \( X_0 \), but it depends also on the amount of computation one is willing to spend on finding small lattice points. As the difference in the upper bounds between (c) and (d) is in the constants only, we see sofar no need to do more extensive computations.

The border \( m = 515,619/515,620 \) in Theorem 3(d) is directly related to how far one wishes to compute the continued fraction expansion of \( \delta \). Note that the difference in the upper bounds is substantial.

The border \( m = 343,118,772/343,118,773 \) in Theorem 3(d) was introduced only because it has some impact on the lower bounds for \( K \) and \( L \). It is therefore not of much significance.

It seems that with the present techniques one cannot go much further. To show the nonexistence of nontrivial \( m \)-cycles for essentially larger ranges of \( m \) an entirely new idea seems to be needed.

Note that if certain values for \( K \) and \( L \) can not be excluded by the approximation lattice method, they can in principle be analyzed for an integer solution of the matrix equation. Without any knowledge on \( k_i \) and \( \ell_i \) such an analysis is very inefficient. Computational and heuristic evidence indicates that for given \( m \) and \( K \) the worst case values for \( k_i \) and \( \ell_i \) can be estimated, and then for any \( m \) an efficient analysis of possible \( m \)-cycles may become feasible. We believe that Lemma 7 is almost sharp for the worst case, in the sense that at best we expect that the factor \( mc_m \) may be improved to a constant, but the exponential dependence on \( m \) in the term \( 2^{-\frac{K}{\log 2}} \) seems unavoidable. Given the state of affairs in transcendence theory, we think that further improvement to Theorem 3 should come from sharpening the lower bounds for \( K \). We leave this for future research.
